- The Density Matrix Renormalization Group (DMRG) was invented by Steve White (student of Ken Wilson) to solve general quantum chain models. [White1992], [White1993]
- Realization that finite-size DMRG leads to MPS: Dukelsky, Martin-Delgado, Nishino, Sierra [Dukelski1998]
- Modern formulation: Vidal [Vidal2003], [Vidal2004], Cirac & Verstraete [Verstraete2004]
- Time evolution: Daley, Kollath, Schollwöck, Vidal [Daley2004], White, Feiguin [White2004]
- Connection to NRG: Weichselbaum, Verstraete, Schollwöck, Cirac, von Delft [arXiv:0504305], [Weichselbaum2009]
- 1. Iterative ground state search

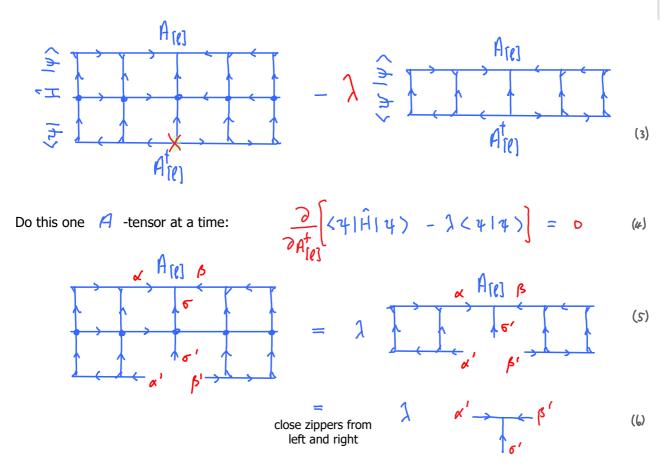

View space of all MPS of given bond dimension, D, as <u>variational</u> space.

Minimize $\langle \psi | H | \psi \rangle$ in this space, subject to constraint of unit normalization, $\langle \psi | \psi \rangle = 1$. (1)

Hence extremize

$$\langle \mathcal{Y}|\hat{H}|\mathcal{Y}\rangle - \hat{J}\langle \mathcal{Y}|\mathcal{Y}\rangle$$
 (2)
 $\int_{\mathcal{L}} \text{Lagrange multiplier}$

Graphical representation, assuming mixed-canonical form w.r.t. site ℓ :

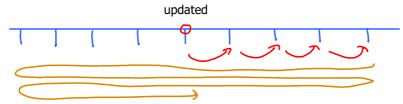

In the notation of (MPS-V.3.11):

 $H_{\alpha}^{\alpha} A_{[e]}^{\alpha} = \lambda A_{[e]}^{\alpha'} \quad \text{with} \quad \alpha' = (\alpha', \sigma', \beta') \quad (7)$

This is an eigenvalue equation for $A_{[\ell]}$ and can be solved with standard linear algebra tools, e.g. Lanczos algorithm (next section).

More generally: if $|\psi\rangle$ is not represented in mixed-canonical form, one obtains a generalized (6) eigenvalue equation of the form HA = NA, with N defined by r.h.s. of (5).

Use that 'eigenvector' $A_{[\ell]}$ yielding lowest eigenvalue (= current estimate of ground state energy) to 'update' MPS, then move to next site, switch to mixed-canonical form of site $\ell_{\ell'}$, optimize $A_{\ell'}$, etc..

'Sweep' back and forth until convergence of ground state energy has been achieved. This works remarkably well for 1D chains with short-ranged interactions.

DMRG-I.2

- Fast way of finding extremal eigenvalues of an Hermitian NxN matrix,
- Prerequiste: an algorithm for computing $| | | \psi \rangle$, for any vector $| \psi \rangle$.

We seek the extremal value of

$$E[|\psi\rangle] = \frac{\langle \psi|H|\psi\rangle}{\langle \psi|\psi\rangle} \qquad (1)$$

Denote extremal value by

$$E_{g} = \min E[147] \equiv E[14g7] \qquad (2)$$

The direction of steepest ascent of the functional E[14], evaluated at 47, is given by

'functional gradient':
$$\frac{\delta \in [1\psi]}{\delta \langle \psi|} \equiv \frac{\mu \langle \psi \rangle}{\langle \psi | \psi \rangle} - \frac{\langle \psi | H | \psi \rangle}{\langle \psi | \psi \rangle^2} | \psi \rangle$$
(3)

$$= \frac{H - E[147]}{\langle 412 \rangle} | 4 \rangle \equiv | 4 \rangle \qquad (4)$$

Moving in opposite direction will thus lower the energy:

 $E[[47 - \alpha] \mathcal{A}_{\alpha}] \leq E[14]$ for small, positive \ll (5)

To find optimal value for α , minimize $\mathbb{E}\left[|\psi\rangle - \alpha |\psi_{\alpha}\rangle \right]$ w.r.t. the 'variational parameter' α , in the space $K_{1} \equiv \operatorname{span}\left\{ |\psi\rangle , |\psi_{\alpha}\rangle \right\} = \operatorname{span}\left\{ |\psi\rangle , |\psi(\psi\rangle) \right\}$. (c) Construct a normalized basis for this space (for a random initial state $|\psi\rangle$):

$$|v_{0}\rangle = \frac{|\psi\rangle}{\sqrt{\langle\psi|\psi\rangle}}$$
(7)

Second basis vector:

$\langle \upsilon_1 | (\$) :$ $b_1 = \overline{\langle \widetilde{\upsilon_1} | \widetilde{\upsilon_1} \rangle} = \langle \upsilon_1 | H | \upsilon_0 \rangle$ (9)

Now find a matrix representation of H in this space: define

$$a_{\circ} \equiv \langle v_{\circ} | H | v_{\circ} \rangle \qquad a_{i} \equiv \langle v_{i} | H | v_{i} \rangle \qquad b_{i} \equiv \langle \tilde{v}_{i} | \tilde{v}_{i} \rangle \qquad (10)$$

c I

First basis vector:

$$\#(v_{0}) \stackrel{(g)}{=} |v_{1}\rangle \langle_{0} + |v_{0}\rangle \alpha_{0} \qquad (n)$$

hence in the space \mathcal{K}_{1} , the Hamiltonian has the matrix representation

((vol H / vo)

Tence in the space $|\mathbf{N}| = r$ the maniforman has the matrix representation

$$H_{K_{1}} = \begin{pmatrix} \langle \upsilon_{0} | H | \upsilon_{0} \rangle & \langle \upsilon_{0} | H | \upsilon_{1} \rangle \\ \langle \upsilon_{1} | H | \upsilon_{0} \rangle & \langle \upsilon_{1} | H | \upsilon_{1} \rangle \end{pmatrix} = \begin{pmatrix} a_{0} & b_{1}^{*} \\ b_{1} & a_{1} \end{pmatrix}$$
(2)

The ground state of H_{k_1} , say g_{k_1} , yields the optimal choice for α .

Now we could iterate: use $\frac{1}{2}$, as starting point for another optimization step. Convergence is rapid. Monitor quality of result by computing the residual energy variance,

 $\tau \left[|\psi\rangle \right] = \left\| \left(|H - E\rangle |\psi\rangle \right\|^{2} = \langle \psi|H^{3}|\psi\rangle - \langle \psi|H|\psi\rangle^{2} \quad (13)$

and stop when it drops below some threshold.

Krylov space

After \mathcal{L} steps, starting from (\mathfrak{v}_{\circ}) , the resulting vector will live in

$$K(1) = span \{ |v_0\rangle, H |v_0\rangle, H^2 |v_0\rangle, \dots, H^L |v_0\rangle \}$$
(4)

= 'Krylov space of
$$H$$
 over (\mathcal{J}_{\diamond}) ' (dimension (\mathcal{I}_{+})). (15)

Instead of repeatedly minimizing in 2x2 subspaces, we could <u>first</u> construct K_L , <u>then</u> compute its ground state. (This is faster, since it amounts to using L <u>simultaneous</u> variational parameters instead of L separate ones.) To do this, iteratively construct a 'Krylov basis' for K_L :

Krylov basis

As before:
normalize
$$\int_{\alpha} |\upsilon_i\rangle = |\widetilde{\upsilon_i}\rangle = \# |\upsilon_0\rangle - \alpha_0 |\upsilon_0\rangle$$
 (16)

Third vector:
$$b_2 h_2 \rangle \equiv |\tilde{v}_2\rangle \equiv H|_{v_1} \rangle - \sum_{j=0}^{1} |v_j\rangle \langle v_j|H|_{v_1}\rangle (17)$$

$$= |H|_{U_1} - |U_2| a_1 - |U_2| b_1^* (18)$$

$$\overline{\langle U_1|H|U_1} - \overline{\langle U_2|H|U_2} b_1^* (18)$$

where

$$b_{2} = \sqrt{\widetilde{\upsilon}_{z}} \widetilde{\upsilon}_{z} = \langle \upsilon_{z} | H | \upsilon_{j} \rangle \qquad (19)$$

$$\langle v_{2} | H | v_{0} \rangle = 0$$
, since $H | v_{0} \rangle \in Span \{ | v_{0} \rangle, | v_{1} \rangle \}$ (20)

Fourth vector:
$$b_{3}(v_{3}) \equiv |\tilde{v}_{3}\rangle \equiv H(v_{2}) - \sum_{j=0}^{2} |v_{j}\rangle\langle v_{j}| H(v_{2})$$
 (21)

$$= |4|\upsilon_{2}\rangle - |\upsilon_{2}\rangle a_{2} - |\upsilon_{1}\rangle b_{2}^{*} - |\upsilon_{2}\rangle o (22)$$

$$(1)$$

$$(1)$$

$$(1)$$

$$(1)$$

$$(20) / (20) /$$

Thus we obtain a two-term iteration scheme: we need to store only 3 vectors at a time!

nth step:
$$b_{n+1}|U_{n+1}\rangle \equiv |\widetilde{U}_{n+1}\rangle = \{f(n) - \sum_{j=0}^{n} |U_j\rangle \langle U_j| + |n\rangle$$
 (23)

=
$$|\{|v_n| - |v_n| a_n - |v_{n-1}| > b_n^{*}$$
 (24)

with
$$a_n = \langle v_n | H | v_n \rangle$$
, $b_n = \langle v_n | H | v_{n-1} \rangle$ (25)

[If it happens that $b_{n+1} = 0$, pick an arbitrary $\int C_{n+1} >$ orthonormal to all $\int C_{n+1} > 0$..., N = 0

Throughout we have:
$$\langle \sigma_{n+1} | H | \sigma_j \rangle = 0$$
 for $j = 0, ..., n - 2$ (26)
since (24)

Hence, rearranging (24): $H(v_n) = |v_{n-1}\rangle b_n^* + |v_n\rangle a_n + |v_{n+1}\rangle b_{n+1}$ (28)

Hence, in
$$K_{L}$$
,
H has tridiagonal form:
H $K_{L} = \begin{pmatrix} a_{\circ} & b_{1}^{*} \\ b_{1} & a_{1} & b_{2}^{*} \\ b_{2} & a_{2} & b_{3}^{*} \\ b_{3} & a_{3} \\ & & & & \\ & & & & \\ & & & & & & \\ & & & & & \\ &$

are the best approximations, within the Krylov space k_{L} , of true ground state energy and ground state. Note: $\left(\psi_{\zeta}^{L}\right)$ can be constructed 'on the fly', one term at a time, by restarting Lanczos iteration from $\left|\upsilon_{o}\right\rangle$ The Lanczos scheme converges exponentially fast, with a rate \sim [gap to first excited state]^{/2}

Thus

Summary

- 1. Start with arbitrary
- 2. First iteration step: (i) $|\widetilde{\mathfrak{V}}_{l}\rangle = H|\mathfrak{V}_{\mathfrak{V}}\rangle$ (ii) $\mathfrak{a}_{\mathfrak{v}} = \langle \widetilde{\mathfrak{V}}_{l}|\mathfrak{V}_{\mathfrak{v}}\rangle$ (iii) $|\widetilde{\mathfrak{V}}_{l}\rangle = |\widetilde{\mathfrak{V}}_{l}\rangle - \mathfrak{a}_{\mathfrak{v}}|\mathfrak{V}_{\mathfrak{v}}\rangle$
- 3. General iteration step, for $N \ge 1$:
 - (i) $\int_{u} = \langle \widetilde{\upsilon}_{n} | \widetilde{\upsilon}_{n} \rangle$
 - (ii) If $b_n \neq o$, then $(v_n) = |\tilde{v_n}|/b_n$

else, pick (v_{w}) as arbitrary normalized vector orthogonal to all (v_{v}) ..., (v_{w-1})

- (iii) $|\widetilde{\mathcal{G}}_{n+1}\rangle = H|_{\mathcal{G}_n}\rangle$
- (iv) $Q_n = \langle \widehat{\mathcal{G}}_{n+1} | \mathcal{U}_n \rangle$
- (v) $|\widetilde{v}_{n+1}\rangle = |\widetilde{v}_{n+1}\rangle |v_n\rangle a_n |v_{n-1}\rangle b_n^*$

and back to 3(i).

There are other ways of organizing this iteration loop, but the one shown here is numerically the most stable. [Paige1972]

3. DMRG for excited states

Suppose we have an MPS representation for ground state, $(g) = (\overline{c}) \prod_{\ell} \beta_{\ell}^{S_{\ell}}$ (1) found by DMRG. Excited states can be constructed repeating a DMRG sweep in space orthogonal to $|g\rangle$.

Extremize:
$$\langle \psi | H | \psi \rangle = \lambda_{i} \langle \psi | \psi \rangle = \lambda_{z} \langle \psi | \varphi \rangle = i$$
 and $\langle \psi | \varphi \rangle = o$. (3)
Extremization w.r.t. $A_{1(z)}^{t}$ yields
 $A_{1(z)}^{t} = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = i$ and $\langle \psi | \varphi \rangle = o$. (3)
Extremization w.r.t. $A_{1(z)}^{t}$ yields
 $A_{1(z)}^{t} = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = i$ and $\langle \psi | \varphi \rangle = o$. (3)
Generic structure of this equation, in mixed-canonical representation of site ℓ [compare (DMRG-1.1.7)]:
 $A_{i}^{t} \wedge A_{1(z)}^{t} = \lambda_{i} A_{i}^{t} + \lambda_{z} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda_{i} \int A_{i}^{t} \langle \psi | \psi \rangle = \lambda$

$$\left[\text{with indices:} \quad P_{g}^{a'}{}_{a} = 1^{a'}{}_{a} - g^{a'}g^{\dagger}_{a}, \text{ so that } P_{g}^{a'}{}_{a}g^{a} = 0\right] \qquad (10)$$

Project (8) onto this subspace:
$$P_{g} H(P_{g+1}) = \lambda_{1} P_{g} A + 0$$
 (11)

DMRG-I.3

$$\frac{(8)=0}{P_g H} P_g (A) = \lambda_1 P_g (A) \qquad (12)$$

This is simply an eigenvalue problem, for $r_{S}H$, in subspace orthogonal to (G). It can be solved using straightforward generalization of Lanczos scheme, using Krylov subspace orthogonal to (G): Given an arbitrary initial state (v_0) , project it onto orthogonal subspace, (v_0) = $r_{S}(v_0)$, and construct new Krylov vectors using

$$|\tilde{\upsilon}_{n+1}\rangle = P_{g}H(\upsilon_{n+1}) - |\upsilon_{n}\ranglea_{n} - |\upsilon_{n-1}\rangleb_{n}^{*} \qquad (14)$$

Why not simply use excited states in K_{L} ? Because numerical noise can cause the $|v_{n}\rangle$ to be not <u>exactly</u> orthogonal, hence for j < n-2, $\langle v_{n} | v_{j} \rangle \simeq ro^{-16}$ rather than 0.

This leads to spurious multiple copies of eigenstates ('ghost states'). For the ground state, the variational principle ensures that the loss of orthogonality does not become a severe problem. But for excited states, it <u>does</u>. To prevent this, explicit reorthogonalization is needed at every step, using $\mathcal{P}_{\mathcal{G}}$, as indicated above.

Block-Lanczos for excited states

Standard Lanczos: represent action of H as

 $H(v_0) = (v_0) A_0 + (v_1) b_1 \Rightarrow$

۵۵	6,4)
6,	a,	b2	
	bz	х. Х.	
		•	

 $\begin{bmatrix} a_{0} \\ b_{1} \end{bmatrix} \begin{bmatrix} b_{1} \\ b_{2} \end{bmatrix} \begin{bmatrix} a_{1} \\ b_{2} \end{bmatrix} \begin{bmatrix} b_{2} \\ b_{2} \end{bmatrix}$

Block-Lanczos: start with set of M orthogonal vectors,

$$H(v_{0,i}) = |v_{0,j}\rangle \delta^{j}_{i} (a_{i})^{i} + |v_{i,j}\rangle (b_{i})^{j}_{i}$$

 (v_0, i) , i = 1, ..., M, and represent action of H as

 $\langle v_{ij} | v_{ij} \rangle = 0$ $\langle v_{ij} | v_{ij} \rangle = \delta_{i}^{j}$

with

and

$$(a_i) = \langle \sigma_{i} | H | \sigma_{i} \rangle$$
 $(b_i) \dot{J}_i = \langle \sigma_{i} | H | \sigma_{i} \rangle$

etc. Then the lowest M eigenstates of block-tridiagonal matrix give the Lanczos approximation for lowest M eigenstates of H

DMRG-I.4

If one encodes symmetries (see Sym-I to Sym-III), then 'one-site update' (discussed above) can get stuck: if one starts in the wrong symmetry sector, one stays there, because one-site update offers no way of <u>enlarging</u> the Hilbert space during the variational search to explore other symmetry sectors. Cure: 'two-site' update, which variationally optimizes two A-tensors at a time.

Represent MPS in mixed-canonical two-site basis:
