Fermionic PEPS

Fermion signs in 2D fermionic tensor networks can be kept track of using two 'fermionization rules'. [Corboz2009] with Vidal and [Corboz2010b] with Evenbly, Verstraete, Vidal first introduced them, for MERA. [Corboz2010b] with Orus, Bauer, Vidal adapted them to PEPS context. This is the approach described in [Bruognolo2020] and presented in this lecture.

Key ingredients: (i) use only positive-parity tensors

(ii) replace line crossings by fermion SWAP gates

Equivalent formulations had also been developed by:

[Barthel2009] with Pineda, Eisert, [Pineda2010] with Barthel, Eisert

[Kraus2010] with Schuch, Verstraete, Cirac

[Shi2009] with Li, Zhao, Zhou

[Bultinck2017a] with Williamson, Haegeman, Verstraete, building on [Bultinck2017] (same

authors); these papers use the mathematical formalism of 'super vector spaces'.

1. Parity conservation

Fermionic Hamiltonians preserve <u>parity</u> of electron number:

$$\hat{P} = \left(-1\right)^{N} \tag{1}$$

۸

$$\hat{H} = \hat{c}^{\dagger}\hat{c} + \hat{c}^{\dagger}\hat{c}\hat{c}^{\dagger}\hat{c} + \hat{c}^{\dagger}\hat{c}^{\dagger} + \hat{c}\hat{c}\hat{c} - (\hat{H}, \hat{P}) = 0 \quad (z)$$

⇒ all energy eigenstates are parity eigenstate, too, hence may be labeled by parity eigenvalue:

So, we may agree to work only with states of well-defined parity.

Example: state space of local fermions,
$$(n_1, n_2, p)$$
 (4)

$$|0\rangle := |0,0;+\rangle; \qquad |1\downarrow\rangle := c_{\downarrow}^{+} c_{\uparrow}^{+} |0\rangle := |1,1;+\rangle$$

$$|1\rangle := c_{\uparrow}^{+} |0\rangle := |1,0;-\rangle, \qquad |1\rangle := c_{\downarrow}^{+} |0\rangle := |0,1;-\rangle, \qquad (5)$$

Every line in tensor network diagram represents a state space, hence also carries a parity index. [When keeping track of abelian symmetries, parity label can be deduced from particle number: $p = (-1)^{Q}$]

F-PEPS.1

Enforcing Z, symmetry [Corboz2010b, Sec.II.F]

To enforce \mathbb{Z}_{z} symmetry on tensor network: choose all terms to be 'parity preserving'.

Rule (i): For every tensor, the total parity is positive:

n-leg tensor:
$$A_{\alpha_1 \alpha_2 \dots \alpha_n} = o$$
 if $P_{\alpha_1 \alpha_2 \dots \alpha_n} := p(\alpha_1) p(\alpha_2) \dots p(\alpha_n) \neq 1$ (6)

Examples:

$$\frac{\alpha}{107} \frac{\beta}{10} \frac{1}{10} = \frac{10,0;+7}{11,0;-7} \qquad P^{\alpha\beta} = P_{\alpha} P_{\beta} P_{\beta}$$

$$\frac{\beta}{11,0;-7} = \frac{11,0;-7}{11,0;-7} \qquad P^{\alpha\beta} = \frac{1}{10,0;-7} + \frac{11,0;-7}{10,0;-7} \qquad P^{\alpha\beta} = \frac{10,0;-7}{10,0;-7} + \frac{10,0;-7}{10,0;-7} + \frac{10,0;-7}{10,0;-7} \qquad P^{\alpha\beta} = \frac{10,0;-7}{10,0;-7} + \frac{10,0;-7}{10,0;-7} \qquad P^{\alpha\beta} = \frac{10,0;-7}{10,0;-7} + \frac{10,0;-7}{10,0;-$$

2. Fermionic signs

F-PEPS.2

$$c_{i} c_{j} = -c_{j} c_{i}$$
, $c_{i} c_{j}^{\dagger} = -c_{j}^{\dagger} c_{i}^{\dagger}$, $c_{i} c_{j}^{\dagger} = \delta_{ij} - c_{j}^{\dagger} c_{i}$

To keep track of these signs, we choose an ordering convention, say 1, 2, ..., N, and define:

$$|l_1, l_2, \dots, l_N\rangle = + C_N \cdots C_2 C_1 |o_1, o_2, \dots, o_N\rangle$$

We have to keep this order in mind when evaluating matrix elements. Example: consider $\lambda = 3$:

 $|\psi\rangle = |0,1,1\rangle = c_3(\frac{1}{2}I_1|0), \quad |\psi'\rangle = |1,1,0\rangle = I_3 c_2(\frac{1}{2}I_1|0)$ $\langle \psi'(c_1'(c_3|\psi)) = \langle 0 \rangle c_1 c_2 c_1'(c_3 c_3 c_2) = -\langle 0|c_1'(c_2'(c_2'(c_1'(0)))) = -I_1'(c_2'(c_2'(c_1'(0))))$ $= I_3$ Let us repeat this computation in MPS language: [Corboz2009, App. A]

Order of vertical lines, from left to right, indicates order of operators acting on $| b \rangle$, from right to left. Horizontal lines show how to move operators in \hat{o} (here $c_1^{\dagger} c_3$) into appropriate 'slots' in $|\psi\rangle$ or $|\psi\rangle$. Line crossings indicate operator swaps. An overall minus sign arises whenever two odd-parity lines cross, because then two fermion operators are exchanged.

SWAP gates

Line crossings keep track of operator orderings.

(-) needed only for exchanging two lines which both host a fermion, i.e. which both have parity (-).

To encode this compactly, introduce SWAP gate whose value depends on parity of incoming lines.

Operators

[Corboz2010b, Sec. III.F]

Some matrix elements of operators involving fermions need minus signs.

Example: spinless fermions, consider two sites i, j, with local basis $\begin{aligned} |\sigma_i \sigma_j \rangle &= (c_j^{\dagger})^{\sigma_j} (c_i^{\dagger})^{\sigma_i} |_{\sigma_i \circ \sigma_j} \rangle, \quad \sigma_i \in \{o, 1\} \end{aligned}$ Two-site operator: $\hat{O} &= \sum |(c_i^{\prime}, c_j^{\prime}) \rangle \hat{O}^{\sigma_i^{\prime}} \hat{\sigma}_i^{\prime} \sigma_j \langle \sigma_i \circ \sigma_j \rangle \rangle, \quad \text{with matrix elements } (i < j) \rangle$ with matrix elements (i < j) $\hat{O}^{\sigma_i^{\prime}} \hat{\sigma}_i^{\prime} \sigma_j \sigma_j \rangle &= \langle \sigma_i^{\prime} \sigma_j^{\prime} | (c_i^{\dagger})^{\sigma_j^{\prime}} \hat{\sigma}_j \langle c_j^{\dagger} \rangle^{\sigma_j^{\prime}} \hat{\sigma}_j \langle c_i^{\dagger} \rangle^{\sigma_j^{\prime}} \langle \sigma_i \circ \sigma_j \rangle \rangle, \quad \text{with matrix elements } (i < j) \rangle$ Examples: $\hat{O} = c_i^{\dagger} c_j^{\prime} , \quad \hat{O}^{\dagger_i \circ j} \hat{O}_{i_i} = \langle \sigma_i \circ_j | (c_i^{\dagger} c_i^{\dagger} c_j \circ \sigma_j^{\dagger}) = +1 \rangle$

$$\hat{o} = c_{j}^{+} c_{i}, \qquad O^{0_{i}} | j_{|i0_{j}} = \langle o_{i} o_{j} | (j_{j} c_{j}^{+} c_{i}^{+} c_{i}^{+} | o_{i} o_{j} \rangle = +1$$

$$\hat{o} = c_{j}^{+} c_{i}, \qquad O^{0_{i}} | j_{|i|_{j}} = \langle o_{i} o_{j} | (c_{j}^{+} c_{i}^{+} | o_{i} o_{j} \rangle) = -1$$

Pairing:

When applying such an operator to a generic state, line crossings appear. These yield additional signs, which can be tracked using rule (ii).

Parity changing tensors

 c^+ and c change parity; but rule (i) demands: use only parity-conserving tensors! Remedy: add additional leg, with index taking just a single value, $\delta := t$ with parity $p(\delta) := (-)$ which compensates for parity change induced by c^+ or c:

Since δ carries just a single value, a SWAP gate involving crossing of δ -line and physical δ -line can be simplified to a parity operator acting on latter:

[Corboz2009, App. C], [Corboz2010b, p. 9]

General argument: parity-preserving tensor has even number of minus-parity lines:

Jump move allows tensor network diagrams to be rearranged according to convenience:

Fermionic order in a PEPS

Choose some ordering for open indices and stick to it!
