

Goal: ground state search for infinite system while exploiting translational invariance.

We will use Vidal's λ notation [see Section 2], but the strategy can be expressed in other notations, too.

Basic idea: 'imaginary time evolution': $\lim_{\beta \rightarrow \infty} e^{-\beta \hat{H}} |\psi\rangle \propto |g\rangle$ (1)

Reason: high-energy states die out quickly (if ground state is gapped):

$$e^{-\beta \hat{H}} = \sum_{\alpha} e^{-\beta E_{\alpha}} |\alpha\rangle \langle \alpha| \xrightarrow{\beta \rightarrow \infty} \underbrace{e^{-\beta E_g}}_{\text{projector onto ground state}} |g\rangle \langle g| \quad (2)$$

↑ complete set of energy eigenstates

1. Trotter decomposition of time evolution operator [Schollwöck2011, Sec. 7.1.1]

General: write Hamiltonian as $\hat{H} = \sum_l \hat{h}_l = \hat{H}_o + \hat{H}_e$ (3)

↑ connects sites l and $l+1$ odd even

Then all odd terms mutually commute, and all even terms mutually commute:

$$[\hat{h}_l, \hat{h}_{l'}] = 0 \quad \text{if } l, l' \text{ are both odd or both even} \quad (5)$$

Divide time interval into N slices: $\beta = \tau N$ (6)

$$e^{-\beta \hat{H}} \stackrel{\text{Trotter decomposition}}{=} \left[e^{-\tau \hat{H}} \right]^N = \left[e^{-\tau (\hat{H}_o + \hat{H}_e)} \right]^N \quad (7)$$

$$\xrightarrow{N \rightarrow \infty, \tau \rightarrow 0} \simeq \left[e^{-\tau \hat{H}_o} e^{-\tau \hat{H}_e} + \mathcal{O}(\tau^2) \right]^N \quad \text{'first order Trotter approx.'} \quad (8)$$

$$\text{or} \quad \simeq \left[e^{-\frac{\tau}{2} \hat{H}_o} e^{-\tau \hat{H}_e} e^{-\frac{\tau}{2} \hat{H}_o} + \mathcal{O}(\tau^3) \right]^N \quad \text{'second order Trotter approx.'} \quad (9)$$

Exploiting (5), odd and even exponents can both be expanded separately without further approximation:

$$e^{-\tau \hat{H}_o} = e^{-\tau \hat{h}_1} e^{-\tau \hat{h}_3} \dots e^{-\tau \hat{h}_{L-1}} := \hat{U}_1 \hat{U}_3 \dots \hat{U}_{L-1} \quad (10a)$$

$$e^{-\tau \hat{H}_e} = e^{-\tau \hat{h}_2} e^{-\tau \hat{h}_4} \dots e^{-\tau \hat{h}_L} := \hat{U}_2 \hat{U}_4 \dots \hat{U}_L \quad (10b)$$

So, when applying $e^{-\beta \hat{H}}$ to $|\psi\rangle$, we can successively apply all odd terms, then truncate, then all even ones, then truncate, etc.

$$e^{-\tau \hat{H}_e} e^{-\tau \hat{H}_o} |\psi\rangle = \text{Diagram (11)} \quad (11)$$

in MPO notation:

$$= \text{Diagram (12)} \quad (12)$$

since \hat{H}_o factorizes, even bonds have dimension $\chi_e = 1$

since \hat{H}_e factorizes, odd bonds have dimension $\chi_o = 1$

All of this can be done for finite chain of length L . But a simplification occurs for $L \rightarrow \infty$

Then we can exploit translational invariance:

Adopt a two-site unit cell (no left- or right-normalization implied).

Step 1: time-evolve 'odd bond':

(first site odd, second site even)

Step 2: time-evolve (updated!) even bond:

(first site even, second site odd)

Iterate until convergence! (To discuss details, we will use \mathcal{M} notation.)

iTEBD is a 'power method': the projector to the ground state is constructed as an increasing number of powers of $e^{-\tau \hat{H}_e} e^{-\tau \hat{H}_o}$.

This is to be contrasted to DMRG ground state search, which is a variational method.

Main advantage of iTEBD: costs not proportional to system size, hence comparatively cheap.

Main disadvantage: loss of orthogonality due to projection, without explicit reorthogonalization.

to be explained below

Usual bond-canonical form of MPS:

$$|\psi\rangle = |\Psi_\alpha\rangle_l |\Phi_\beta\rangle_{l+1} [S_l]^{\alpha\beta} \quad (1)$$

Choose S diagonal, and call it Λ (following Vidal):

$$|\psi\rangle = \sum_{\alpha} |\Psi_\alpha\rangle_l |\Phi_\alpha\rangle_{l+1} [\Lambda_l]^{\alpha\alpha} \quad (\text{Schmidt decomposition}) \quad (2)$$

Then reduced density matrices of left and right parts are diagonal, with eigenvalues $(\Lambda_l^{\alpha\alpha})^2$:

$$\rho_L = \text{Tr}_R |\psi\rangle\langle\psi| = \sum_{\alpha} |\Psi_\alpha\rangle_l \underbrace{[\Lambda_l]^{\alpha\alpha} [\Lambda_l^\dagger]_{\alpha\alpha}}_{[\rho_{L,L}]^{\alpha\alpha}} \langle\Psi_\alpha|, \quad (3)$$

$$\rho_R = \text{Tr}_L |\psi\rangle\langle\psi| = \sum_{\alpha} |\Phi_\alpha\rangle_{l+1} \underbrace{[\Lambda_l^\dagger]_{\alpha\alpha} [\Lambda_l]^{\alpha\alpha}}_{[\rho_{R,R}]^{\alpha\alpha}} \langle\Phi_\alpha|, \quad (4)$$

Vidal introduced MPS representation in which Schmidt decomposition can be read off for each bond:

$$|\psi\rangle = \underbrace{\Gamma_1}_{\sigma_1} \underbrace{\Lambda_1}_{\sigma_2} \underbrace{\Gamma_2}_{\sigma_3} \underbrace{\Lambda_2}_{\sigma_4} \dots \underbrace{\Gamma_l}_{\sigma_l} \underbrace{\Lambda_l}_{\sigma_{l+1}} \underbrace{\Gamma_{l+1}}_{\sigma_{l+2}} \dots \underbrace{\Gamma_L}_{\sigma_L} \quad (5)$$

where Λ_l = diagonal matrix, consisting of Schmidt coefficients for bond l between sites l and $l+1$:

$$|\psi\rangle = |\Psi_\alpha\rangle_l |\Phi_\alpha\rangle_{l+1} \Lambda_l^{\alpha\alpha}, \quad \rho_{L,L} := \Lambda_l \Lambda_l^\dagger = \Lambda_l^\dagger \Lambda_l =: \rho_{L,R} \quad (6)$$

with orthonormal sets on L:

$$\langle\Psi^{\alpha'}|\Psi_\alpha\rangle_l = \mathbb{1}^{\alpha'\alpha} \quad (7)$$

and on R:

$$\langle\Phi^{\beta'}|\Phi_\beta\rangle_{l+1} = \mathbb{1}^{\beta'\beta} \quad (8)$$

Any MPS can always be brought into $\Gamma\Lambda$ form. Proceed in same manner as when left-normalizing, [cf. MPS-I.4]

$$|\psi\rangle = |\vec{\sigma}\rangle_l (M^{\sigma_1} \dots M^{\sigma_L}) \quad (9)$$

Successively use SVD on pairs of adjacent tensors:

$$MM' = \underbrace{USV^T}_{\tilde{A}} \tilde{M}' := A \tilde{M}, \quad (10)$$

to bring MPS into left-canonical form,

store singular values, $\Lambda_\ell := S_\ell$ and at end define

$$A_\ell^{\sigma_\ell} =: \Lambda_{\ell-1} \Gamma_\ell^{\sigma_\ell}, \quad \Lambda_0 = 1 \quad (11)$$

physical index σ_ℓ of A_ℓ is associated with Γ_ℓ

$$|\psi\rangle = \text{Diagram with tensors } A_1, A_2, \dots, A_\ell, A_{\ell+1} \text{ connected in a chain.} \quad (12)$$

$$=: \text{Diagram showing the decomposition of } A_\ell \text{ into } \Lambda_{\ell-1}, \Gamma_\ell, \text{ and } \Lambda_\ell. \quad (13)$$

Note: in numerical practice, this involves dividing by singular values, $\Gamma_\ell^{\sigma_\ell} := \Lambda_{\ell-1}^{-1} A_\ell^{\sigma_\ell}$ (14)

So, first truncate states for which $S_{\ell-1}^{\alpha\alpha} = 0$, (15)

Even then, the procedure can be numerically unstable, since arbitrarily small singular values may arise.

So, truncate states for which (say) $S_{\ell-1}^{\alpha\alpha} < 10^{-8}$. In practice, this should be done in (16)

any case, because when computing norms and matrix elements, singular value s contributes weight s^2 and when $s^2 < 10^{-16}$, its contribution gets lost in numerical noise. Inverting the remaining singular values, $s > 10^{-8}$, is unproblematic in numerical practice.

Similarly, if we start from the right, SVDs yield right-normalized B -tensors, and we can define

$$B_\ell^{\sigma_\ell} =: \Gamma_\ell^{\sigma_\ell} \Lambda_\ell, \quad \Lambda_\ell = 1, \quad \text{Diagram showing } B_\ell \text{ decomposition.} \quad (17)$$

i.e. $\Gamma_\ell^{\sigma_\ell} := B_\ell^{\sigma_\ell} \Lambda_\ell^{-1}$ (18)

So, relation between standard bond-canonical form and 'canonical $\Gamma\Lambda$ form' is:

$$|\psi\rangle = \text{Diagram showing the relation between standard and canonical forms.} \quad (19)$$

$$1 = A_\ell^\dagger A_\ell = \Gamma_\ell^\dagger \Lambda_{\ell-1}^\dagger \Lambda_{\ell-1} \Gamma_\ell = \Gamma_\ell^\dagger \rho_{\ell-1,R} \Gamma_\ell, \quad \text{Diagram showing the contraction of } \Lambda \text{ tensors.} \quad (20)$$

$$1 = B_L B_L^\dagger = \Gamma_L \Lambda_L \Lambda_L^\dagger \Gamma_L^\dagger = \Gamma_L \rho_{L,L} \Gamma_L^\dagger, \quad \} = \begin{array}{c} B_L \\ B_L^\dagger \end{array} = \begin{array}{c} \Gamma_L \Lambda_L \\ \Gamma_L^\dagger \Lambda_L^\dagger \end{array} = \begin{array}{c} \Gamma_L \\ \Gamma_L^\dagger \end{array} \rho_{L,L} \quad (21)$$

(20), (21) guarantee the orthonormality properties (7), (8)

If Γ_L has very small singular values, Γ_L must have large elements! Can lead to unstable behavior...

For infinite, translationally invariant system, use two-site unit cell, $\begin{array}{c} M_o \quad M_e \\ \text{---} \end{array}$, repeated periodically.
(to avoid cluttering, σ indices on Λ, A are not displayed, but implicitly understood)

Each iTEBD iteration involves two steps, updating first odd bonds, then even bonds:

$|\psi\rangle = \dots \rightarrow \begin{array}{c} M_o \quad M_e \quad M_o \quad M_e \quad M_o \\ \text{---} \end{array} \dots$
 $:= \dots (\Lambda_e \Gamma_o) (\Lambda_o \Gamma_e) (\Lambda_e \Gamma_o) (\Lambda_o \Gamma_e) (\Lambda_e \Gamma_o) \dots$

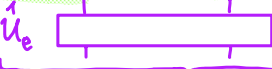

1. update odd bonds:

\hat{U}_o 

$\dots (\Lambda_e \tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_e \Lambda_e) \tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_e \Lambda_e \tilde{\Gamma}_o \dots$

yields new $\tilde{\Gamma}_o \tilde{\Lambda}_o \tilde{\Gamma}_o$
insert these throughout chain
but leave Λ_e unchanged (2a)

2. update even bonds:

\hat{U}_e 

$\dots \tilde{\Lambda}_e \tilde{\Gamma}_o (\tilde{\Lambda}_o \tilde{\Gamma}_e \tilde{\Lambda}_e \tilde{\Gamma}_o \tilde{\Lambda}_o) \tilde{\Gamma}_e \tilde{\Lambda}_e \tilde{\Gamma}_o$

yields new $\tilde{\Gamma}_e \tilde{\Lambda}_e \tilde{\Gamma}_o$
insert these throughout chain
but leave $\tilde{\Lambda}_o$ unchanged (2b)

Then rename $\tilde{\Lambda}_{o,e} \rightarrow \Lambda_{o,e}$, $\tilde{\Gamma}_{o,e} = \Gamma_{o,e}$, and iterate.

Step 1: Time-evolve odd bond $\Gamma_o \Lambda_o \Gamma_e$
and its environment $\Lambda_e \dots \Lambda_e$

$$\hat{U}_o := e^{-\tau \hat{h}_o} = \begin{array}{c} \uparrow \bar{\sigma}_o \quad \uparrow \bar{\sigma}_e \\ \text{---} \\ \uparrow \sigma_o \quad \uparrow \sigma_e \end{array} \quad (3)$$

contract,
reshape,
= SVD

truncate,
normalize [see (7)]
= reshape

$\begin{array}{c} U \quad S \quad V^\dagger \\ \text{---} \end{array}$
 left-normalized \tilde{A}_o $\tilde{\Lambda}_o$ right-normalized \tilde{B}_e

(4a)

(4b)

define

$$\tilde{\Gamma}_o := \Lambda_e^{-1} \tilde{A}_o$$

$$\tilde{\Gamma}_e := \tilde{B}_e \Lambda_e^{-1}$$

reinststate Λ_e

$$= \begin{array}{c} \Lambda_e \quad \tilde{\Lambda}_o \quad \tilde{\Gamma}_e \quad \Lambda_e \\ \text{---} \end{array} \quad (5)$$

define

$$\tilde{M}_e := \tilde{\Lambda}_o \tilde{\Gamma}_e = \tilde{\Lambda}_o \tilde{B}_e \Lambda_e^{-1}$$

left-normalized \tilde{A}_o $\tilde{\Lambda}_o$ \tilde{M}_e not right-normalized

$$:= \begin{array}{c} \Lambda_e \quad \tilde{\Gamma}_o \quad \tilde{\Lambda}_o \quad \tilde{\Gamma}_e \quad \Lambda_e \\ \text{---} \end{array} \quad (6)$$

\hat{U}_o is not a unitary operation, hence reduces norm. Thus, $\tilde{\Lambda}_o$ is normalized to unity by hand:

$$\tilde{\Lambda}_o := \frac{S_{\text{trunc}}}{[\text{Tr}(S_{\text{trunc}}^\dagger S_{\text{trunc}})]^{1/2}}, \text{ then } \begin{array}{c} \tilde{A}_o \quad \tilde{\Lambda}_o \quad \tilde{B}_e \\ \text{---} \end{array} = \begin{array}{c} \tilde{\Lambda}_o \\ \text{---} \end{array} = \text{Tr} \tilde{\Lambda}_o^\dagger \tilde{\Lambda}_o = 1. \quad (7)$$

(6) completes update of odd bond. The updated MPS now has the form $|\tilde{\psi}\rangle = \prod_{\sigma} \tilde{A}_o \tilde{M}_e \tilde{A}_o \tilde{M}_e \dots$ (8)

Updated bond energy :

$$\bar{h}_{\text{bond}} = \frac{1}{2}(\bar{h}_o + \bar{h}_e) \approx$$

consider only two sites

ignore tensors describing rest of chain

Updating odd bond lowers \bar{h}_o , slightly raises \bar{h}_e ('odd bond much happier, even bond slightly unhappier').

Step 2: Time-evolve even bond $\tilde{\Lambda}_e \Lambda_e \tilde{\Gamma}_o$ and its environment $\tilde{\Lambda}_o \dots \tilde{\Lambda}_o$

$$\hat{U}_e := e^{-\tau \hat{h}_e} = \frac{\uparrow \tilde{\sigma}_e}{\uparrow \sigma_e} \quad (10)$$

contract, reshape, SVD, \approx reshape, truncate, normalize, reinstate

$$\text{with normalization } \text{Tr } \hat{\Lambda}_e^\dagger \tilde{\Lambda}_e = 1 \quad (12)$$

define

$$\begin{aligned} \tilde{\Gamma}_e &:= \tilde{\Lambda}_o^{-1} \tilde{A}_e \\ \tilde{\Gamma}_o &:= \tilde{B}_o \tilde{\Lambda}_o^{-1} \\ \tilde{M}_o &:= \tilde{\Lambda}_e \tilde{\Gamma}_o = \tilde{\Lambda}_e \tilde{B}_o \tilde{\Lambda}_o^{-1} \end{aligned}$$

left-normalized \tilde{A}_e \tilde{M}_o not right-normalized

$$= \quad (13)$$

(12) completes update of even bond. Updated MPS now has the form $|\tilde{\psi}\rangle = \prod_{\sigma} |\tilde{\sigma}\rangle \tilde{M}_o \tilde{A}_e \tilde{M}_o \tilde{A}_e$ (14)

Compute updated bond energy using (9), with $o \leftrightarrow e$.

Updating even bond lowers \bar{h}_e , slightly raises \bar{h}_o ('even bond much happier, odd bond slightly unhappier').

Now iterate: rename $\tilde{M}_{o,e} \rightarrow M_{o,e}$, $\tilde{\Lambda}_{o,e} \rightarrow \Lambda_{o,e}$, $\tilde{\Gamma}_{o,e} \rightarrow \Gamma_{o,e}$

then apply \hat{U}_o , then \hat{U}_e , etc.) until convergence is reached (monitor ground state energy...)

Remarks:

1. In principle, computation of $\tilde{\Lambda}_o^{-1}$, $\tilde{\Lambda}_e^{-1}$ can become unstable, because singular values can be very small. Thus: truncate by discarding smallest singular values $\approx 10^{-8}$, only then invert.

2. Note that \tilde{A}_o is left-normalized, but $\tilde{M}_e \stackrel{(6,5)}{=} \tilde{\Lambda}_o \tilde{B}_e \tilde{\Lambda}_e^{-1}$ is not! 'Loss of orthogonality'.
 $\tilde{M}_o \stackrel{(13,11)}{=} \tilde{\Lambda}_e \tilde{B}_o \tilde{\Lambda}_o^{-1}$

This causes problems when computing expectation values. For example, odd bond energy, given by

does not reduce to (9), because zippers can not be closed from left and right. Hence (9) involves an approximation, namely ignoring the rest of the chain.

4. iTEBD: Hastings' method (optional)

iTEBD.4

[Hastings2009, Sec. II.A], [Schollwöck2011, Sec. 7.3.2]

Goal: avoid 'reinstatement' of Λ_e, Λ_o , since this requires inverting singular-value matrix.

(i.e. dividing by small singular values)

Write

$$|\psi\rangle = \begin{array}{c} \text{M}_o \quad \text{M}_e \quad \text{M}_o \\ \Lambda_e \quad \Gamma_o \quad \Lambda_o \quad \Gamma_e \quad \Lambda_e \quad \Gamma_o \quad \Lambda_o \\ \text{odd bond} \quad \text{B}_o \quad \text{B}_e \quad \text{B}_o \quad \text{even bond} \end{array} \quad (1)$$

with

$$\text{M}_o = \Lambda_e \Gamma_o, \quad \text{M}_e = \Lambda_o \Gamma_e, \quad \text{B}_o = \Gamma_o \Lambda_o, \quad \text{B}_e = \Gamma_e \Lambda_e \quad (2)$$

Step 1: Time-evolve odd bond $\text{M}_o \Lambda_o \text{B}_e$ to define $\tilde{\Lambda}_o \tilde{\Lambda}_o \tilde{\text{B}}_e$ via SVD, and $\tilde{\text{M}}_e$ via contraction.

(instead of reinstatement of Λ_e)

Step 2: Time-evolve even bond $\tilde{\text{M}}_e \Lambda_e \text{B}_o$ to define $\tilde{\Lambda}_e \tilde{\Lambda}_e \tilde{\text{B}}_o$ via SVD, and $\tilde{\text{M}}_o$ via contraction.

(instead of reinstatement of $\tilde{\Lambda}_o$)

Then rename $\tilde{\text{M}}_{o,e} \rightarrow \text{M}_{o,e}$, $\tilde{\Lambda}_{o,e} \rightarrow \Lambda_{o,e}$, $\tilde{\text{B}}_{o,e} = \text{B}_{o,e}$, and iterate.

Step 1 (odd-even): Compute

$$\hat{\text{U}}_o \begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} = \begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} = \begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} \quad (3)$$

known from initialization, or previous iteration

left-normalized

right-normalized

Do SVD on

$$\begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} \Lambda_e = \begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} \Lambda_e \begin{array}{c} \sigma_o \quad \sigma_e \end{array} = \begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} \Lambda_e \begin{array}{c} \sigma_o \quad \sigma_e \end{array} \quad (4)$$

SVD yields updated tensors $\tilde{\Lambda}_o, \tilde{\Lambda}_e, \tilde{\text{B}}_e$. Note that the outgoing leg of $\tilde{\Lambda}_o$ involves a truncation, governed by $\tilde{\Lambda}_o$. Since this is also the incoming leg of what will be called $\tilde{\text{M}}_e$, we need a definition of the latter involving a truncation governed by $\tilde{\Lambda}_o$ on its incoming leg. This is achieved by left-contraction with $\tilde{\Lambda}_o^\dagger$:

$$\tilde{\text{M}}_e^{\sigma_e} := \tilde{\Lambda}_o^\dagger \tilde{\Lambda}_o \tilde{\text{B}}_e^{\sigma_e} \quad [\text{symbol } \text{M} \text{ denotes: not left-normalized, see (7)}] \quad (5)$$

(Note: no inversion of singular matrix required!) Justification for this definition:

(2) $\tilde{\Lambda}_e$

$$\begin{array}{c} \tilde{\Lambda}_o^\dagger \tilde{\Lambda}_o \tilde{\text{B}}_e^{\sigma_e} \end{array} \begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} = \begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} \begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} \begin{array}{c} \text{M}_o \quad \text{M}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} \quad (6)$$

$$\tilde{\Lambda}_o^\dagger \tilde{\Lambda}_o = \mathbb{1}$$

$$\begin{array}{c} \tilde{\Lambda}_o \quad \tilde{\Lambda}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} = \begin{array}{c} \tilde{\Lambda}_o \quad \tilde{\Lambda}_e \\ \Lambda_o \quad \Lambda_e \end{array} \begin{array}{c} \sigma_o \quad \sigma_e \end{array} \quad (7)$$

$$\tilde{A}_o^T \tilde{A}_o^{\sigma_o} = 1 \quad = \quad \text{diagram with } \tilde{\Lambda}_o \text{ and } \tilde{\Gamma}_e \text{ tensors} \quad \stackrel{(5)}{=} \quad \text{diagram with } \tilde{M}_e \text{ tensor} \quad (7)$$

where we associated $\tilde{\Gamma}_e := \tilde{B}_e \Lambda_e^{-1}$ and $\tilde{M}_e := \tilde{\Lambda}_o \tilde{\Gamma}_e$ by analogy to (2) [but did not need Λ_e^{-1} explicitly!] (8)

This concludes step 2. We now have updated tensors

$$M_o \rightarrow \tilde{A}_o, \quad \Lambda_o \rightarrow \tilde{\Lambda}_o, \quad B_e \rightarrow \tilde{B}_e, \quad M_e \rightarrow \tilde{M}_e, \quad \text{but not updated } \Lambda_e, B_o$$

Step 2 (even-odd): Compute

$$\text{diagram with } \tilde{M}_e \text{ and } \tilde{A}_o \text{ tensors} \quad =: \quad \text{diagram with } \Phi_e^{\sigma_e \sigma_o} \text{ tensor} \quad (9)$$

known from step 1:

$$\text{Do SVD on } \Phi_e^{\sigma_e \sigma_o} \tilde{\Lambda}_o = \text{diagram with } \tilde{A}_e, \tilde{\Lambda}_e, \tilde{B}_o \text{ tensors} \quad \stackrel{\text{SVD}}{=} \quad \text{diagram with } \tilde{A}_e, \tilde{\Lambda}_e, \tilde{B}_o \text{ tensors} \quad (10)$$

left-normalized right-normalized

$\tilde{\Lambda}_e^+ \tilde{\Lambda}_e = 1$

$\tilde{M}_o \tilde{\Lambda}_o$

The SVD yields updated tensors $\tilde{A}_e, \tilde{\Lambda}_e, \tilde{B}_o$, and \tilde{A}_e has a $\tilde{\Lambda}_e$ truncation on its outgoing leg, i.e. incoming leg of what will be called \tilde{M}_o , so we need a definition of the latter with $\tilde{\Lambda}_e$ on incoming leg:

This is achieved by:

$$\tilde{M}_o^{\sigma_o} := \tilde{A}_e^+ \Phi_e^{\sigma_e \sigma_o} \quad [\text{not left-normalized, see (12)}] \quad (11)$$

Justification:

$$\tilde{A}_e^+ \Phi_e^{\sigma_e \sigma_o} \stackrel{(9)}{=} \text{diagram with } \tilde{A}_e, \tilde{\Lambda}_o, \tilde{\Lambda}_o^{-1} \text{ tensors} \stackrel{(10)}{=} \text{diagram with } \tilde{A}_e, \tilde{\Lambda}_e, \tilde{B}_o, \tilde{\Lambda}_o^{-1} \text{ tensors} \stackrel{(12)}{=} \text{diagram with } \tilde{M}_o \text{ tensor} \quad (12)$$

not left-normalized

where we associated $\tilde{\Gamma}_o := \tilde{B}_o \tilde{\Lambda}_o^{-1}$ and $\tilde{M}_o := \tilde{\Lambda}_e \tilde{\Gamma}_o$ by analogy to (2) [but did not need $\tilde{\Lambda}_o^{-1}$ explicitly!] (13)

This concludes step 2. We now have updated tensors

$$\tilde{M}_e \rightarrow \tilde{A}_e, \quad \Lambda_e \rightarrow \tilde{\Lambda}_e, \quad B_o \rightarrow \tilde{B}_o, \quad M_o \rightarrow \tilde{M}_o \quad \text{without changing } \tilde{\Lambda}_o, \tilde{B}_e$$

Now iterate (apply \hat{U}_o , then \hat{U}_e , etc.) until convergence of bond energy is reached.

Compute bond energy using (iTEBD3.9) for step 1, or its $o \leftrightarrow e$ version for step 2.

Concluding remarks:

Main advantage of iTEBD: costs not proportional to system size, hence comparatively cheap.

Main disadvantage: loss of orthogonality due to projection, without explicit reorthogonalization.

Needed for computing correlators via transfer matrix.

Definition: an infinite, translationally invariant MPS with two-site unit cell, expressed in the form [Orus2008]

$(14) =$

is called 'two-site canonical' if $A_{0,e}$ are left-normalized and $B_{0,e}$ are right-normalized:

Figure 1 consists of four pairs of diagrams, labeled (za), (zb), (zc), and (zd). Each pair shows a circuit element on the left, followed by an equals sign, and then a vertical line representing the dual element on the right. (za) shows a voltage source A_o in series with a voltage source A_o^t . (zb) shows a voltage source A_e in series with a voltage source A_e^t . (zc) shows a voltage source B_o in series with a voltage source B_o^t . (zd) shows a voltage source B_e in series with a voltage source B_e^t .

Correlators can then be computed using transfer matrix methods:

$\langle \hat{O}_l \hat{O}_{l'} \rangle =$

(2)

close zippers

$$=$$

Problem: iTEBD (including Hastings' version) yields infinite MPS that are not in canonical form, due to loss of orthogonality. It is possible to restore orthogonality (albeit at the cost of inverting singular value matrices).

Strategy: given $\{\rho_e, \lambda_e, \rho_o, \lambda_o\}$:
2-site unit cell

Step 1: 'coarse-grain' to get $\{\Gamma, \Lambda\}$:
 1-site unit cell
 $\Gamma := c_e \lambda_e \Gamma_o$ $\Lambda := \Lambda_o$

Step 2: bring into 1-site canonical form $\{\tilde{\rho}, \tilde{\lambda}\}$:
 1-site unit cell

A diagram of a 1D lattice with alternating sites and hopping parameters. The lattice is represented by a horizontal line with alternating open and filled circles. Above the line, the hopping parameters are labeled: λ_0 (above an open circle), t_e (above a filled circle), λ_e (above an open circle), t_0 (above a filled circle), and so on. Below the line, orange brackets group the parameters into pairs: (λ_0, t_e) , (λ_e, t_0) , (λ_0, t_e) , (λ_e, t_0) , and (λ_0, t_e) . Each pair is labeled with a double exclamation mark $!!$ below the bracket. The diagram illustrates the periodicity of the hopping parameters in the lattice.

Step 2: bring into 1-site canonical form $\{\tilde{r}, \tilde{\lambda}\}$:  (5)
 (how? will be explained further below)

Definition of 1-site canonical:

$$\tilde{\lambda}^2 := \begin{array}{|c|} \hline \tilde{\lambda} \\ \hline \tilde{\lambda}^\dagger \\ \hline \end{array} = \tilde{\lambda}$$

$$\tilde{\lambda}^2 \begin{array}{|c|} \hline \tilde{r} \\ \hline \tilde{r}^\dagger \\ \hline \end{array} = \uparrow \quad (6a)$$

$$\begin{array}{|c|} \hline \tilde{r} \\ \hline \tilde{r}^\dagger \\ \hline \end{array} \tilde{\lambda}^2 = \uparrow \quad (6b)$$

Step 3: 'fine-grain' via SVD,
reinststate $\tilde{\lambda}_o := \tilde{\lambda}$

$$\tilde{\lambda} \tilde{r} \tilde{\lambda} \quad \text{SVD} \quad \tilde{\lambda}_o \tilde{r} \tilde{\lambda}_o \quad \text{reinststate}$$

$$\begin{array}{c} \text{left-canonical} \quad \text{right-canonical} \\ \tilde{\lambda}_o \tilde{\lambda}_o^{-1} \tilde{A}_e \tilde{\lambda}_e \tilde{B}_o \tilde{\lambda}_o^{-1} \tilde{\lambda}_o \end{array} \quad (7)$$

define $\{\tilde{r}_e, \tilde{\lambda}_e, \tilde{r}_o, \tilde{\lambda}_o\}$
2-site unit cell

$$\begin{array}{c} \tilde{\lambda}_o \tilde{r}_e \tilde{\lambda}_e \tilde{r}_o \tilde{\lambda}_o \end{array} \quad (8)$$

with $\tilde{\lambda}_o := \tilde{\lambda} \quad (9a), \quad \tilde{\lambda}_o \tilde{r}_e := \tilde{A}_e \quad (9b), \quad \tilde{r}_o \tilde{\lambda}_o := \tilde{B}_o \quad (9c), \quad \tilde{r}_e \tilde{\lambda}_e \tilde{r}_o = \tilde{r} \quad (9d)$

Claim: $\{\tilde{r}_e, \tilde{\lambda}_e, \tilde{r}_o, \tilde{\lambda}_o\}$ constructed in this manner (via (6)), is in the desired 2-site canonical form.

Proof: Since \tilde{A}_e and \tilde{B}_o were obtained via SVD, they are left- and right-normalized, respectively. Hence:

$$\tilde{\lambda}_o^2 \begin{array}{|c|} \hline \tilde{r}_e \\ \hline \tilde{r}_e^\dagger \\ \hline \end{array} \stackrel{(9a)}{=} \begin{array}{|c|} \hline \tilde{A}_e \\ \hline \tilde{A}_e^\dagger \\ \hline \end{array} = \uparrow \quad \checkmark \quad (10a) \quad \text{as required by (3b)}$$

$$\begin{array}{|c|} \hline \tilde{r}_o \\ \hline \tilde{r}_o^\dagger \\ \hline \end{array} \tilde{\lambda}_o^2 \stackrel{(9b)}{=} \begin{array}{|c|} \hline \tilde{B}_o \\ \hline \tilde{B}_o^\dagger \\ \hline \end{array} = \uparrow \quad \checkmark \quad (10b) \quad \text{as required by (3c)}$$

Moreover:

$$\begin{array}{|c|} \hline \tilde{r}_o \\ \hline \tilde{r}_o^\dagger \\ \hline \end{array} \begin{array}{|c|} \hline \tilde{r}_e \\ \hline \tilde{r}_e^\dagger \\ \hline \end{array} \stackrel{(10a)}{=} \begin{array}{|c|} \hline \tilde{\lambda}_o^2 \\ \hline \tilde{\lambda}_o^2 \\ \hline \end{array} \begin{array}{|c|} \hline \tilde{r}_e \\ \hline \tilde{r}_e^\dagger \\ \hline \end{array} \stackrel{(9a, 9d)}{=} \begin{array}{|c|} \hline \tilde{r} \\ \hline \tilde{r}^\dagger \\ \hline \end{array} \stackrel{(6a)}{=} \uparrow \quad \checkmark \quad (11a)$$

and:

$$\begin{array}{|c|} \hline \tilde{r}_e \\ \hline \tilde{r}_e^\dagger \\ \hline \end{array} \begin{array}{|c|} \hline \tilde{r}_o \\ \hline \tilde{r}_o^\dagger \\ \hline \end{array} \stackrel{(10b)}{=} \begin{array}{|c|} \hline \tilde{\lambda}_e^2 \\ \hline \tilde{\lambda}_e^2 \\ \hline \end{array} \begin{array}{|c|} \hline \tilde{r}_o \\ \hline \tilde{r}_o^\dagger \\ \hline \end{array} \stackrel{(9a, 9b)}{=} \begin{array}{|c|} \hline \tilde{r} \\ \hline \tilde{r}^\dagger \\ \hline \end{array} \stackrel{(6b)}{=} \uparrow \quad \checkmark \quad (11b)$$

Eq. (6) was assumed to hold when constructing $\{\tilde{r}_e, \tilde{\lambda}_e, \tilde{r}_o, \tilde{\lambda}_o\}$

Back to step 2: How to bring arbitrary $\{r, \lambda\}$ into 1-site canonical form $\{\tilde{r}, \tilde{\lambda}\}$:
not 1-site canonical

Starting point:

(henceforth we draw single line for double physical index)

$$\begin{array}{|c|} \hline r \\ \hline r^\dagger \\ \hline \end{array} \lambda^2 \neq \uparrow \quad \begin{array}{|c|} \hline \lambda \\ \hline \lambda^\dagger \\ \hline \end{array} r^2 \neq \uparrow \quad (12)$$

Thus, corresponding 'transfer matrices' are not normalized:

$$\begin{array}{|c|} \hline R \\ \hline \end{array} = \begin{array}{|c|} \hline r \lambda \\ \hline \lambda^\dagger r^\dagger \\ \hline \end{array} \neq \uparrow \quad \begin{array}{|c|} \hline L \\ \hline \end{array} = \begin{array}{|c|} \hline \lambda r \\ \hline r^\dagger \lambda^\dagger \\ \hline \end{array} \neq \uparrow \quad (13)$$

$$\begin{array}{c} \text{R} \\ \text{---} \end{array} = \begin{array}{c} \uparrow \quad \uparrow \\ \text{---} \end{array} \quad , \quad \begin{array}{c} \text{R} \\ \text{---} \end{array} \neq \begin{array}{c} \text{---} \end{array} \quad \begin{array}{c} \text{L} \\ \text{---} \end{array} = \begin{array}{c} \uparrow \quad \uparrow \\ \text{---} \end{array} \quad , \quad \begin{array}{c} \text{L} \\ \text{---} \end{array} \neq \begin{array}{c} \text{---} \end{array} \quad (13)$$

Def: if M is hermitian and positive semidefinite, its 'principal square root' satisfies $M^{1/2} M^{1/2} = M$ and $M^{1/2\dagger} = M^{1/2}$.

To construct $M'^{1/2}$, diagonalize $M = W D W^\dagger = \underbrace{W D^{1/2} W^\dagger}_{M'^{1/2}} \underbrace{W D^{1/2} W^\dagger}_{M'^{1/2}}$ and define $M'^{1/2} = W D^{1/2} W^\dagger$. (14)

Find dominant right- or left-eigenvectors of R and L , and take their principal square root:

$$\begin{aligned} \text{largest eigenvalue } V_R &= X X^\dagger \\ V_L &= Y^\dagger Y \end{aligned} \quad (15c) \quad (15d)$$

Now divide one leg of each \angle by a 'square root':

Then

[to cancel factors of X and Y when computing normalization in (15)]

So,  might yield a properly normalized transfer matrix. Express MPS through such an object.

Define new Λ via SVD:

$$Y \wedge X = \alpha \tilde{\lambda} v^+$$

$$u^\dagger u = \mathbb{1}, \quad v^\dagger v = \mathbb{1}$$

factors into

factors into $\tilde{r} = V^T X^{-1} F Y^{-1} u$

[illegible]

(18)

Claim: $\{\tilde{\tau}, \tilde{\lambda}/\eta\}$ is in the desired 2-site canonical form.

Proof: Since u and v^t were obtained via SVD, they satisfy

(17) $y \wedge x$ (20b) R

$$u^+ \quad u \quad = \quad \mathbb{1} \quad (20a)$$

$V^+ V = \mathbb{1}$ (20b)

Proof. Since U and V were obtained via SVD, they satisfy

$$V^+ V = \mathbb{1} \quad (20b)$$

Hence

Diagrammatic proof of equation (20b) using tensor network notation. The proof starts with a diagram (18) showing a loop with tensors \tilde{r}^\dagger and $\tilde{\lambda}^\dagger$. This is transformed through several steps: (20a) introduces tensors V , $X^{-1\dagger}$, and $Y^{-1\dagger}$; (13) introduces a rotation R ; (14c) introduces V_R ; (16a) shows a contraction with a vertical line; and (19b) shows the final result γ .

Thus, $\{\hat{r}, \hat{\lambda}/\sqrt{\eta}\}$ satisfies (6b), as required!

Similarly:

Diagrammatic proof of equation (20a) using tensor network notation. The proof starts with a diagram (18) showing a loop with tensors \tilde{r}^\dagger and $\tilde{\lambda}^\dagger$. This is transformed through several steps: (20a) introduces tensors U , V^\dagger , X^{-1} , and Y^{-1} ; (13) introduces a rotation L ; (14d) introduces V_L ; (16b) shows a contraction with a vertical line; and (19b) shows the final result γ .

Thus, $\{\hat{r}, \hat{\lambda}/\sqrt{\eta}\}$ satisfies (6a), as required!
